ALPAQUITA and Air-Shower Reconstruction

ALPACA : **SDs** $\simeq 400 + 4$ **MDs** area

ALPAQUITA(this study) : 1/4-scale surface array of ALPACA
97 **SDs** / No **MD** / a prototype array

Gamma ray or BG cosmic ray

Air shower (μ, γ, e)

Surface air shower Detectors (SDs)

Measure secondary air-shower particles

- ① Particle density $\rightarrow$ Energy estimation
- ② Arrival time $\rightarrow$ Direction estimation

Underground Muon Detectors (MDs)

Muon counting $\rightarrow \gamma$ / CR separation

This study focuses on energy estimation using **SD information.**

Monte Carlo Setup for Energy Estimation^{7/19}

Gamma-ray energy reconstruction is studied using MC simulation
→ γ / CR separation is not included in this study.

Simulation

- CORSIKA 7.6400
- Geant4 10.04.p02
- Hadronic model: EPOS-LHC / FLUKA

MC conditions 10^8 gamma-ray events

- Primary: **gamma rays**
- Energy: **0.3 TeV – 10 PeV**
- Zenith angle: **$< 60^\circ$**
- Spectral index: **-2.0**
- Shower cores: **within 300 m from the array center**

Simulation flow

Generation of primary gamma rays
& AS simulation with CORSIKA

Detector response simulation with Geant4

Event reconstruction/Energy estimation

Energy-estimation performance
is evaluated by comparing
estimated and true energies.

Energy Estimator 1: $\Sigma \rho$

$\Sigma \rho$: Total particle density measured by the surface detectors

larger $\Sigma \rho \rightarrow$ higher Energy $\rightarrow \Sigma \rho$ can be used as an energy estimator

Energy Estimator 2: S_x

S_x : Particle density at x meters from the shower axis

$$\rho_{\text{NKG}}(r) = \frac{N_e}{r_m^2} \frac{\Gamma(4.5 - s)}{2\pi \Gamma(s) \Gamma(4.5 - 2s)} \left(\frac{r}{r_m}\right)^{s-2} \left(1 + \frac{r}{r_m}\right)^{s-4.5}$$

Fit the lateral distribution with the NKG function

Lateral particle distribution (1 MC)

Used in other AS experiments

Telescope Array : S_{800}

Tibet AS γ : S_{50}

The optimal distance depends on the array.
 → Need to determine the optimal value of x for ALPAQUITA.

Two Goals of This Study

1. Optimize the distance x for the S_x energy estimator for ALPAQUITA
→ which x is the best resolution for ALPAQUITA?
2. Compare the optimized S_x with conventional estimators
→ Can S_x improve the energy resolution?

K. Kawata et al., Exp. Astron. 44, 1–9 (2017).

→ Investigate whether an optimized S_x can also improve the energy resolution

Zenith-independent Energy Estimation

1. Divide events into S_x bins
2. Determine representative **true energy** in each bin
3. Fit the representative points with a quadratic function

Previous ALPAQUITA studies used this method with $\Sigma \rho$.

S. Kato et al., Exp. Astron. 52, 85–107 (2021).

Zenith-dependent Energy Estimation

Shower development depends on the zenith angle.

→ Fit the S_x –energy relation in each $\sec \theta$ range.

a clear zenith angle dependence of the S_x and energy relation.

in each $\sec \theta$ data → each fit function

$$\log_{10} E = a_i + b_i(\log_{10} S_x) + c_i(\log_{10} S_x)^2$$

Different zenith angles give different energy-estimation relations.

Zenith-dependent Energy Estimation

The discrete fit parameters a_i , b_i , and c_i depend on $\sec \theta$.

→ **Fitting these parameters as smooth functions of $\sec \theta$.**

$$\begin{aligned} a(\sec \theta) &= p0_a + p1_a * \sec \theta + p2_a * (\sec \theta)^2 \\ b(\sec \theta) &= p0_b + p1_b * \sec \theta + p2_b * (\sec \theta)^2 \\ c(\sec \theta) &= p0_c + p1_c * \sec \theta + p2_c * (\sec \theta)^2 \end{aligned}$$

continuous conversion function

$$\begin{aligned} \log_{10} E &= c(\sec \theta) \times (\log_{10} S_x)^2 \\ &+ b(\sec \theta) \times (\log_{10} S_x) + a(\sec \theta) \end{aligned}$$

Improved energy estimation using both S_x and zenith angle

Zenith-Dependent vs Zenith-Independent method

Energy resolution vs E_{Rec} ($0 < \theta < 40^\circ$)

Energy bias vs E_{Rec} ($0 < \theta < 40^\circ$)

Zenith-dependent method gives better performance.

→ **Zenith-dependent method is used in the following analysis.**

Optimal Distance for S_x : 40 m

S_{30} and S_{40} :
gives best resolution

S_{40} : slightly better
above 100 TeV
→ Select S_{40} for the
following analysis

→ compare the other estimators

Comparison the performance of S_{40} and $\Sigma \rho$

16/19

Energy resolution vs E_{Rec} ($0 < \theta < 40^\circ$)

Energy bias vs E_{Rec} ($0 < \theta < 40^\circ$)

S_{40} gives better performance at high energies (above 30 TeV).

Low energy: the resolutions are similar

→ S_{40} requires at least 16 hit detectors (N_{hit}) for the lateral fit.

→ What happens if the N_{hit} requirement is relaxed?

Low-Energy Performance with N_{hit} Cuts

The lateral fit **requires at least 16 hit detectors**, limiting S_{40} at low energies.
 → We relax the N_{hit} requirement from **16 to 8 and 4**.

$N_{\text{hit}} \geq 16$ does not reach the low-energy region.

For $N_{\text{hit}} \geq 4$ or 8 , $\Sigma \rho$ gives better performance than S_{40} at low energies.

→ @ low E, we use low N_{hit} $\Sigma \rho$

Energy-Dependent Choice of Estimator

18/19

Based on the resolution, different conditions are adopted for low and high energies.

High Energy $\rightarrow N_{\text{hit}} 16 S_{40}$
Low Energy $\rightarrow N_{\text{hit}} 4, 8 \Sigma \rho$

These conditions are used in the ALPAQUITA future analysis.

We performed an optimization of the energy estimation for ALPAQUITA.

1. Zenith-angle-dependent S_x energy estimation was optimized for ALPAQUITA.

The shower lateral distribution and zenith angle are used together to estimate the primary energy.

2. S_{40} gives the best high-energy performance.

Among S_{20} – S_{70} , S_{40} gives the best overall resolution above ~ 10 TeV.

Compared with the conventional $\Sigma\rho$ method, the resolution is improved, with a small energy bias of about 5% or less at high energies.

3. Different estimators are used for high- and low-energy events.

S_{40} requires enough hit detectors for the lateral fit and is effective mainly above ~ 1 TeV. At lower energies, $\Sigma\rho$ with a lower N_{hit} threshold is adopted.

→ **Energy reconstruction was established from a few TeV to the PeV region.**

Back up

A_{eff} for the ALPAQUITA

the effective area strongly depends on the N_{hit} requirement.

Improvement over the conventional method

Energy resolution vs E_{Rec} ($0 < \theta < 40^\circ$)

S_{40} zenith dependent
Representative **peak fit**

$\Sigma \rho$ zenith Independent
Representative **mmean**

The new S_{40} method gives better energy resolution over most of the energy range.

Why does S_{40} outperform $\Sigma\rho$?

- For showers near the array edge, $\Sigma\rho$ misses particles falling outside the array and tends to underestimate the shower size.
- S_{40} is derived from a fitted lateral distribution, making it less sensitive to partial shower containment.

Particles falling outside the finite detector array are not measured, so their contribution is lost in $\Sigma\rho$.

Possible origin of the low-energy recovery

- At low energies, only a small fraction of events can reconstruct S_{40} .
 - The selected events may be biased toward well-reconstructed showers.
- The apparent improvement is likely due to a selection effect, not an intrinsic improvement of S40

Abnormal Structures in the $\Sigma \rho$ Distribution

Mis-reconstructed shower-core position

High-energy showers with cores outside the array can be mis-reconstructed as having cores inside the array.

Only a small part of the shower is detected, making them appear similar to lower-energy showers.

Structure mainly seen for $\Sigma \rho$

$\Sigma \rho$ is directly affected by large signals from detectors close to the shower core.

Therefore, fluctuations in the core region can produce a large deviation in $\Sigma \rho$.

S40 is less sensitive to this effect because it is obtained from a lateral fit without directly using the innermost region around the shower core.

Procedure for Determining Representative Points

1. Binning of the scatter plot

- Events are divided into bins of S_{40} .
- Each bin is required to contain at least 25 events.
- The bin center is used as the representative S_{40} value.

2. Peak fit in each projected distribution

- For each S_{40} bin, the true-energy distribution is projected.
- The distribution is binned uniformly in $\log(E)$.
- A Gaussian fit is performed around the peak.
- The fitted peak value is taken as the representative energy.

Energy Resolution Achieved in This Work

S40 provides the best resolution above several tens of TeV.

At 100 TeV, $\sigma_{\ln E} \approx 0.18$, corresponding approximately to an 18% fractional energy spread.

$$\sigma \text{ of } \ln E = \sigma [\ln(E_{\text{rec}}/E_{\text{true}})]$$

	3TeV	10TeV	30TeV	100TeV	300TeV
N_{hit} 4 $\Sigma \rho$	0.65	0.55	0.36	0.28	0.22
N_{hit} 8 $\Sigma \rho$	/	0.48	0.36	0.28	0.22
N_{hit} 16 S_{40}	/	/	0.32	0.18	0.13

Is the current performance sufficient?

- **This work achieves $\sigma_{\ln E} \approx 0.18$ at 100 TeV with S_{40} .**
 - This performance is already comparable to other major air-shower experiments.
 - Further improvement in energy resolution is still valuable.
 - However, at the $\sim 10\%$ level, absolute energy-scale uncertainty also becomes important.
- **→ The current performance is meaningful, while further improvement should be considered together with energy-scale calibration.**

How Is Energy Reconstructed in Other Air-Shower Experiments?

A common approach is to use the shower signal at an optimal distance from the core. ALPAQUITA S_{40} , Tibet S_{50} , and KM2A ρ_{50} are based on the same general idea.

Experiment	Main energy estimator	Reconstruction
ALPAQUITA	S_{40}	Lateral fit $\rightarrow \mathbf{S}_{40} \rightarrow E(S_{40}, \theta)$
Tibet AS γ	S_{50}	Modified-NKG fit $\rightarrow \mathbf{S}_{50} \rightarrow$ zenith- in dependent energy
LHAASO-KM2A	ρ_{50}	ED lateral fit $\rightarrow \mathbf{\rho}_{50} \rightarrow$ zenith-dependent polynomial
HAWC	Ground Parameter / NN	Lateral signal at ~ 40 m or neural network

Representative Energy Resolution around 100 TeV

The present ALPAQUITA performance is comparable to other major air-shower arrays at around 100 TeV.

Experiment / method	Reported metric	Representative resolution
This work — ALPAQUITA S_{40}	$\sigma[\ln(E_{\text{rec}}/E_{\text{true}})]$	$\approx 0.18 \rightarrow \approx 18\%^*$
Tibet S_{50} MC	log-energy response width	$\approx 16\%$
LHAASO-KM2A	half-width of central 68%	$\approx 13\%$
HAWC NN	$\sigma_{\log_{10} E}$	$\approx 23\text{--}25\%$ equivalent*
HAWC GP	$\sigma_{\log_{10} E}$	$\approx 30\%$ equivalent*

Definitions and analysis conditions are not identical among experiments.

***Approximate fractional resolution using $\sigma_E/E \approx \sigma_{\ln E}$ for small fluctuations.**

***HAWC values are approximate conversions from log-space resolution.**

What Limits the Energy Resolution?

- **Energy resolution can be improved by optimizing the energy estimator and including shower-development information.**
 - Zenith-angle dependence reduces systematic shower-development effects.
 - Additional parameters such as shower age may further improve the estimation.
 - However, intrinsic shower-to-shower fluctuations remain.
 - These include fluctuations in the first interaction and subsequent shower development.
- **Therefore, the achievable resolution is ultimately limited by both shower fluctuations and reconstruction accuracy.**

What Is New in This Analysis?

- **New within ALPAQUITA**

- First implementation of **zenith-angle-dependent S_x energy estimation**
- Systematic optimization of the reference distance: $S_{20}-S_{70} \rightarrow S_{40}$
- Study of the **hit-detector requirement for the lateral fit**, including low-energy efficiency
- Optimization of the estimator over a **wide energy range**

- **In the broader field**

- The basic concept is **not new worldwide**
- Similar approaches are already used in other air-shower experiments
e.g. S_{50} in LHAASO-KM2A, S_{50} in Tibet As γ (not zenith)
- **The key point of this work is to optimize the method specifically for ALPAQUITA**

Total E resolution & E bias

- $S_{40} \ N_{\text{hit}} \geq 16$
- -●- - $\Sigma \rho \ N_{\text{hit}} \geq 16$
- $S_{40} \ N_{\text{hit}} \geq 8$
- -●- - $\Sigma \rho \ N_{\text{hit}} \geq 8$
- $S_{40} \ N_{\text{hit}} \geq 4$
- -●- - $\Sigma \rho \ N_{\text{hit}} \geq 4$

Energy resolution vs E_{Rec} ($0 < \theta < 40^\circ$)

Energy bias vs E_{Rec} ($0 < \theta < 40^\circ$)
